

I. Summary of Activities This Week:

- Maxwell completed the VM connection between attack and vulnerable machine
- Brock designed and submitted the UML flowchart for us to follow in our project
- Mitch researched Hippi standards to see how we could configure the vulnerable machine like a hospital system would look and what attacks could be used
- Solomon and Brock determined the attacks that will be implemented. The structure of each attack will follow recon, initial access, privilege escalation, credential access, then the main purpose of each attack which is attempting to exfiltrate data or disrupt systems.
- A rough python UML was created to outline certain variables and processes to be made

II. Progress Made:

- Design was further refined, extending to defining what functions will be used in each python file and what variables are needed.
- Scope was focused into specific attacks, mainly focusing testing exfiltration and ransomware attacks as the overall goal of the attack framework.

III. Challenges or Issues Encountered:

- Figuring out if we wanted separate python files for each system, ex: decision engine, recon, and attack. We decided to use multiple files

IV. Plans for Next Week:

- Begin coding, creating a rough structure for further development of the framework.
- Any necessary research in relation to implementation.
